Control Structures in Java
if-else and switch

Lecture 4
CGS 3416 Spring 2017

January 23, 2017
Control Flow

Control flow refers to the specification of the order in which the individual statements, instructions or function calls of an imperative program are executed or evaluated.
Types of Control Flow

Flow of control through any given function is implemented with three basic types of control structures:

- **Sequential**: Default mode. Statements are executed line by line.
- **Selection**: Used for decisions, branching – choosing between 2 or more alternative paths.
  - if
  - if - else
  - switch
  - conditional statements
- **Repetition**: Used for looping – repeating a piece of code multiple times in a row.
  - while
  - do - while
  - for

The function construct, itself, forms another way to affect flow of control through a whole program. This will be discussed later in the course.
Logical Operators
Logical Operators

Java has Boolean operators for combining expressions. Each of these operators returns a Boolean value: a true or a false.

!x  // the NOT operator (negation) – true if x is false

x && y  // the AND operator – true if both x and y are true

x || y  // the OR operator – true if either x or y (or both) are true

x \&\& y  // the EXCLUSIVE OR operator – true if exactly one operand is true and one is false

These operators will be commonly used as test expressions in selection statements or repetition statements (loops).
Relational Operators

The comparison operators in Java work much like the symbols we use in mathematics. Each of these operators returns a Boolean value: a true or a false.

\[
\begin{align*}
x &== y \quad // \; x \; \text{is equal to} \; y \\
x &!= y \quad // \; x \; \text{is not equal to} \; y \\
x &< y \quad // \; x \; \text{is less than} \; y \\
x &\leq y \quad // \; x \; \text{is less than or equal to} \; y \\
x &> y \quad // \; x \; \text{is greater than} \; y \\
x &\geq y \quad // \; x \; \text{is greater than or equal to} \; y
\end{align*}
\]
Examples of Expressions

\[(x > 0 && y > 0 && z > 0) \text{ // all three of } (x, y, z) \text{ are positive}\]

\[(x < 0 || y < 0 || z < 0) \text{ // at least one of the three variables is negative}\]

\[(\text{numStudents } \geq 20 && ! (\text{classAvg } < 70)) \text{ // there are at least 20 students and the class average is at least 70}\]

\[(\text{numStudents } \geq 20 && \text{classAvg } \geq 70) \text{ // means the same thing as the previous expression}\]
Short Circuit Evaluation

- The `&&` and `||` operators also have a feature known as short-circuit evaluation.
- In the Boolean AND expression `(X && Y)`, if `X` is false, there is no need to evaluate `Y` (so the evaluation stops). Example:

  \[(d != 0 && n / d > 0)\]

- Notice that the short circuit is crucial in this one. If `d` is 0, then evaluating `(n / d)` would result in division by 0 (illegal). But the "short-circuit" prevents it in this case. If `d` is 0, the first operand `(d != 0)` is false. So the whole `&&` is false.

- Similarly, for the Boolean OR operation `(X || Y)`, if the first part is true, the whole thing is true, so there is no need to continue the evaluation. The computer only evaluates as much of the expression as it needs. This can allow the programmer to write faster executing code.
The most common selection statement is the if statement. Basic syntax:

```
if (boolean expression)
{
    statement(s)
}
```

The condition is always a boolean expression. This means that it must be an expression that evaluates to a true or a false.
if - else Statements

- The if statement can also have an else clause. This is sometimes known as an if/else statement. Basic syntax:

```java
if (boolean expression)
{
    statement(s)
}
else
{
    statement(s)
}
```

- In both of these formats, the set braces can be left out if the “body” of the if or the else is a single statement. Otherwise, the block is needed.
Examples

- if (grade >= 68)
  
  System.out.print("Passing");

- if (x == 0)
  
  System.out.println("Nothing here");
  else
  
  System.out.println("There is a value");
Examples

```java
if (y != 4)
{
    System.out.println("Wrong number");
    y = y * 2;
    counter++;
}
else
{
    System.out.println("That's it!");
    success = true;
}
```
Examples

- Be careful with ifs and elses. If you don’t use {}, you may think that you’ve included more under an if condition than you really have.

```java
if (val < 5)
    System.out.println("True");
else
    System.out.println("False");
System.out.println("Too bad!");
```

- Indentation is only for people! It improves readability, but means nothing to the compiler.
Some Common Errors

What’s wrong with these if-statements? Which ones are syntax errors and which ones are logic errors?

- if (x == 1 || 2 || 3)
  System.out.print("x is a number in the range 1-3");

- if (x > 5) && (y < 10)
  System.out.print(“Yahoo!”);

- if (response != ‘Y’ || response != ‘N’)
  System.out.print("You must type Y or N (for yes or no)");
Nested if-statement

We could add more valid statements between the set braces, including valid if statements:

```java
if ( x > 10 )
{
    x /= 10;
    System.out.println(x);
    if ( x > 10 )
    {
        x /= 10;
        System.out.println(x);
    }
}
else
    System.out.println("x is less than 10");
```
find the first valid conditional expression in the series that evaluates to true,

execute the java statement immediately under it, and then to skip the remainder of the series.

```java
if (temperature <= 95) // low body temperature
    System.out.println("low body temperature");
else if (temperature > 101) // fever
    System.out.println("fever!");
else // normal temperature
    System.out.println("normal");
```
Order Matters

the example to print out "big" if a number is bigger than 100, "medium" if a number is between 20 and 100, and "small" otherwise.

- if (num > 100)
  System.out.println("Big");
  else if (num > 20)
    System.out.println("Medium");
  else
    System.out.println("Small");

- if (num > 20)
  System.out.println("Big");
  else if (num > 100)
    System.out.println("Medium");
  else
    System.out.println("Small");
Exercise

- Figuring a letter grade
- Have the user enter a number from 1 to 12 corresponding to the index of the month. The program then prints out the name of the month
A switch statement is often convenient for occasions in which there are multiple cases to choose from. The syntax format is:

```java
switch (expression)
{
    case constant:
        statements
    case constant:
        statements
    ...(as many case labels as needed)
    default: // optional label
        statements
}
```
The switch Statement

- The switch statement evaluates the expression, and then compares it to the values in the case labels. If it finds a match, execution of code jumps to that case label.

- The values in case labels must be constants, and may only be types char, byte, short, or int. From Java 7 onwards, Strings and Enum types are also allowed. It must be of the same type with the expression.
  - This also means the case label must be a literal or a variable declared to be constant (with final).
  - You may not have case labels with regular variables, floating point literals, operations, or function calls.

- If you want to execute code only in the case that you jump to, end the case with a break statement, otherwise execution of code will “fall through” to the next case. The all statements after the match are executed including those in the subsequent cases.
The switch Statement

switch (expression)
{
    case constant:
        statements
        break;
    case constant:
        statements
        break;
    ...(as many case labels as needed)
    default: // optional label
        statements
}

Lecture 4CGS 3416 Spring 2017
The day is Weekday or Weekend?

switch (day)
{
    case 2:
    case 3:
    case 4:
    case 5:
    case 6:
        name = "Weekday";
    case 1:
    case 7:
        name = "Weekend";
}
System.out.println("It is a " + name);
Exercise

- Figuring a letter grade with `Switch(Grades2-2.java)`
- Have the user enter a number from 1 to 12 corresponding to the index of the month. The program then prints out the name of the month
- Converts the day of the in numeric form (1, 2, ... 7) to the name of the day (Monday, ..., Sunday) (`DayName.java`)
There is a special operator known as the conditional operator that can be used to create short expressions that work like if/else statements.

- **Format:**
  
  \[
  \text{boolean} \text{ \_expr} ? \text{true} \text{ \_expr} : \text{false} \text{ \_expr}
  \]

- **How it works:**
  
  - The boolean expression is evaluated for true/false value. This is like the test expression of an if-statement.
  - If the expression is true, the operator returns the true expression value.
  - If the test expression is false, the operator returns the false expression value.

- Note that this operator takes three operands. It is the one ternary operator in the Java language.
Some Examples

```java
System.out.print((x > y) ? "x is greater than y" : "x is less than or equal to y");

// Note that this expression gives the same result as the following

if (x > y)
    System.out.print("x is greater than y");
else
    System.out.print("x is less than or equal to y");
```
Some Examples

(x < 0 ? value = 10 : value = 20);

// this gives the same result as:

value = (x < 0 ? 10 : 20);

// and also gives the same result as:

if (x < 0)
    value = 10;
else
    value = 20;
